# From "On a Method for the Evaluation of Maxima and Minima"<sup>1\*</sup>

(Fermat obtained a general method to find the extrema of a given function. His algorithm was subsequently developed into the method of the "characteristic triangle,"  $dx$ ,  $dy$ , and  $ds$ .)

– PIERRE DE FERMAT

The whole theory of evaluation of maxima and minima presupposes two unknown quantities and the following rule:

Let  $a$  be any unknown of the problem (which is in one, two, or three dimensions, depending on the formulation of the problem). Let us indicate the maximum or minimum by  $a$  in terms which could be of any degree. We shall now replace the original unknown  $a$  by  $a + e$  and we shall express thus the maximum or minimum quantity in terms of  $a$  and  $e$  involving any degree. We shall adequate [adégaler], to use Diophantus' term,<sup>2</sup> the two expressions of the maximum or minimum quantity and we shall take out their common terms. Now it turns out that both sides will contain terms in  $e$  or its powers. We shall divide all terms by  $e$ , or by a higher power of  $e$ , so that  $e$  will be completely removed from at least one of the terms. We suppress then all the terms in which  $e$  or one of its powers will still appear, and we shall equate the others; or, if one of the expressions vanishes, we shall equate, which is the same thing, the positive and negative terms. The solution of this last equation will yield the value of  $a$ , which will lead to

the maximum or minimum, by using again the original expression.

Here is an example:

To divide the segment  $AC$  [Fig. 70.1] at  $E$  so that  $AE \times EC$  may be a maximum.

Figure 70.1

We write  $AC = b$ ; let  $a$  be one of the segments, so that the other will be  $b - a$ , and the product, the maximum of which is to be found, will be  $ba - a^2$ . Let now  $a + e$  be the first segment of  $b$ ; the second will be  $b - a - e$ , and the product of the segments,  $ba - a^2 + be - 2ae - e^2$ ; this must be adequated with the preceding:  $ba - a^2$ . Suppressing common terms:  $be \sim 2ae + e^2$ . Suppressing  $e$ :  $b = 2a$ .<sup>[3]</sup> To solve the problem we must consequently take the half of  $b$ .

We can hardly expect a more general method.

## On the Tangents of Curves

We use the preceding method in order to find the tangent at a given point of a curve.

Let us consider, for example, the parabola  $BDN$  [Fig. 70.2] with vertex  $D$  and of diameter  $DC$ ; let  $B$  be a point on it at which the line  $BE$  is to be drawn tangent to the parabola and intersecting the diameter at  $E$ .

We choose on the segment  $BE$  a point  $O$  at which we draw the ordinate  $OI$ ; also we construct

\* SOURCE: This translation from the *Oeuvres de Fermat*, edited by P. Tannery and C. Henry, appears in D. J. Struik, ed., *A Source Book in Mathematics, 1200–1800* (1969), 223–27. It is reprinted with permission of Harvard University Press, Copyright © 1969 by the President and Fellows of Harvard College.

the axis  $IA$  by any plane  $BN$  and put  $IN = e$ , so that  $NA = b - e$ .

It is clear that in this figure and in similar ones (parabolas and paraboloids) the centers of gravity of segments cut off by parallels to the base divide the axis in a constant proportion (indeed, the argument of Archimedes can be extended by similar reasoning from the case of a parabola to all parabolas and paraboloids of revolution<sup>8</sup>). Then the center of gravity of the segment of which  $NA$  is the axis and  $BN$  the radius of the base will divide  $AN$  at a point  $E$  such that  $NA/AE = IA/AO$ , or, in formula,  $b/a = (b - e)/AE$ .

The portion of the axis will then be  $AE = (ba - ae)/b$  and the interval between the two centers of gravity,  $OE = ae/b$ .

Let  $M$  be the center of gravity of the remaining part  $CBRV$ ; it must necessarily fall between the points  $N, I$ , inside the figure, in view of Archimedes' postulate 9 in *On the equilibrium of planes*, since  $CBRV$  is a figure completely concave in the same direction.<sup>9</sup>

But

$$\frac{\text{Part } CBRV}{\text{Part } BAR} = \frac{OE}{OM},$$

since  $O$  is the center of gravity of the whole figure  $CAV$  and  $E$  and  $M$  are those of the parts.

Now in the paraboloid of Archimedes,

$$\frac{\text{Part } CAV}{\text{Part } BAR} = \frac{IA^2}{NA^2} = \frac{b^2}{b^2 + e^2 - 2be},$$

hence by dividing,

$$\frac{\text{Part } CBRV}{\text{Part } BAR} = \frac{2be - e^2}{b^2 + e^2 - 2be}.$$

But we have proved that

$$\frac{\text{Part } CBRV}{\text{Part } BAR} = \frac{OE}{OM}.$$

Then in formulas,

$$\frac{2be - e^2}{b^2 + e^2 - 2be} = \frac{OE (= ae/b)}{OM},$$

hence

$$OM = \frac{b^2ae + ae^3 - 2bae^2}{2b^2a - be^2}.$$

From what has been established we see that the point  $M$  falls between points  $N$  and  $I$ ; thus  $OM$

$< OI$ ; now, in formula,  $OI = b - a$ . The question is then prepared from our method, and we may write

$$b - a \sim \frac{b^2ae + ae^3 - 2bae^2}{2b^2e - be^2}.$$

Multiplying both sides by the denominator and dividing by  $e$ :

$$2b^3 - 2b^2a - b^2e + bae \sim b^2a + ae^2 - 2bae.$$

Since there are no common terms, let us take out those in which  $e$  occurs and let us equate the others:

$$2b^3 - 2b^2a = b^2a, \text{ hence } 3a = 2b.$$

Consequently

$$\frac{IA}{AO} = \frac{3}{2}, \text{ and } \frac{AO}{OI} = \frac{2}{1},$$

and this was to be proved.<sup>10</sup>

The same method applies to the centers of gravity of all the parabolas ad infinitum as well as those of paraboloids of revolution. I do not have time to indicate, for example, how to look for the center of gravity in our paraboloid obtained by revolution about the ordinate;<sup>11</sup> it will be sufficient to say that, in this conoid, the center of gravity divides the axis into two segments in the ratio 11/5.

## Struik's Notes

1. This paper was sent by Fermat to Father Marin Mersenne, who forwarded it to Descartes. Descartes received it in January 1638. It became the subject of a polemic discussion between him and Fermat (*Oeuvres*, I, 133). On Mersenne, see Selection I.6, note 1, of Struik.
2. See Selection IV.7, note 5 [of Struik].
3. Our notation is modern. For instance, we have written (following the French translation in *Oeuvres*, III, 122)  $be \sim 2ae + e^2$ , Fermat wrote:  $B$  in  $E$  adaequabitur  $A$  in  $E$  bis +  $Eq$  ( $Eq$  standing for  $E$  quadratum). The symbol  $\sim$  is used for "adequates."
4. Fermat wrote:  $D$  ad  $D - E$  habebit majorem proportionem quam  $Aq.$  ad  $Aq. + Eq. - A$  in  $E$  bis ( $D$  will have to  $D - E$  a larger ratio than  $A^2$  to  $A^2 + E^2 - 2AE$ ).
5. See the letters from Fermat to Roberval, written in 1636 (*Oeuvres*, III, 292-94, 296-97).
6. The gist of this method is that we change the variable  $x$  in  $f(x)$  to  $x + e$ ,  $e$  small. Since  $f(x)$  is stationary near a maximum or minimum (Kepler's remark),  $f(x + e) - f(x)$

goes to zero faster than  $e$  does. Hence, if we divide by  $e$ , we obtain an expression that yields the required values for  $x$  if we let  $e$  be zero. The legitimacy of this procedure remained, as we shall see, a subject of sharp controversy for many years. Now we see in it a first approach to the modern formula:

$$f'(x) = \lim_{e \rightarrow 0} \frac{f(x + e) - f(x)}{e},$$

introduced by Cauchy (1820-21).

7. This paper seems to have been sent in a letter to Mersenne written in April 1638, for transmission to Roberval. Mersenne reported its contents to Descartes. Fermat used the term "parabolic conoid" for what we call "paraboloid of revolution."

8. "All parabolas" means "parabolas of higher order,"  $y = kx^n$ ,  $n > 2$ . The reference is to Archimedes' *On Floating Bodies*, II, Prop. 2 and following; see T. L. Heath, *The Works of Archimedes* (Cambridge University Press, Cambridge, England, 1897; reprint, Dover, New York), 264ff.
9. This is postulate 7 in the modern Heiberg edition, and is translated in Heath, p. 190, as follows: "In any figure whose perimeter is concave in (one and) the same direction the center of gravity must be within the figure." (On the term "concave in the same direction," see Heath, p. 2.)
10. These relations were known to Archimedes (see note 8). But Fermat solved this problem on centers of gravity, hence a problem in the integral calculus, with what we might call an application of the principle of virtual variations.
11. Here  $ACI$  of Fig. 70.3 is rotated about  $CI$ .

## ROBERVAL. THE CYCLOID

*To Generate the Cycloid.* Let the diameter  $AB$  [Fig. 1] of the circle  $AEGB$  move along the tangent  $AC$ , always remaining parallel to its original position, until it takes the position  $CD$ , and let  $AC$  be equal to the semicircle  $AGB$ . At the same time, let the point  $A$  move on the semicircle  $AGB$ , in such a way that the speed of  $AB$  along  $AC$  may be equal to the speed of  $A$  along the semicircle  $AGB$ . Then, when  $AB$  has reached the position  $CD$ , the point  $A$  will have reached the position  $D$ . The point  $A$  is carried along by two motions—its own on the semicircle  $AEGB$ , and that of the diameter along  $AC$ . The path of the point  $A$ , due to these two motions, is the half cycloid  $A \dots D$ , the second half being symmetrical with the first.

Fig. 1

*Proposition 3. To construct a tangent to the cycloid.*

*Construction.* Let  $R_2$  be the given point at which the tangent is to be drawn. Draw  $R_2R_1$  parallel to  $AC$ . Draw  $R_2U$  tangent to the generating circle  $RR_2$  and make  $R_2U = R_2R_1$ . Complete the parallelogram  $R_2UVR_1$ , and draw the diagonal  $R_2V$ . Then  $R_2V$  is the required tangent.

*Proof.* The direction of the motion of the point  $R_2$  which is due to the motion of  $AB$  along  $AC$  is  $R_2R_1$ ; the direction of the motion of the point  $R_2$  which is due to the motion of the point  $A$  on the circumference is  $R_2U$ , and since these motions are always equal, it follows that  $R_2R_1$  must equal  $R_2U$ . Therefore  $R_2V$  is the tangent to the cycloid at  $R_2$ , since it is the resultant of the two motions.

*Addendum.* If, instead of being equal, the magnitudes of the two motions had been in some other ratio, the parallelogram would have been constructed with its sides in that ratio.<sup>4</sup>

<sup>2</sup> The "companion of the cycloid" is a sine curve. If  $AC$  is taken as the  $X$ -axis,  $AB$  as the  $Y$ -axis, its equation is, in our notation,  $y = 1 - \cos x$ .

<sup>3</sup> When arc  $AE = \varphi$  [radius  $R = 1$ ], then the equation of the cycloid is  $x = \varphi - \sin \varphi$ ,  $y = 1 - \cos \varphi$ , and the area  $AM_2DM_1A = \int_0^\pi (\varphi - \varphi + \sin \varphi)^2 dy = \int_0^\pi \sin^2 \varphi d\varphi = \pi/2$ .

<sup>4</sup> The tangent construction uses kinematic concepts and is related to the method of Archimedes in his book *On spirals*; see T. L. Heath, *The works of Archimedes* (Cambridge University Press, Cambridge, England, 1897; reprint, Dover, New York), 151ff, esp. Props. 16–20. While Roberval used Greek methods to find tangents, his contemporary Fermat was laying the foundations of the present method, based on the derivative (see Selection IV.8).

DESCARTES

## 11.A9 The method of normals

[1] The angle formed by two intersecting curves can be as easily measured as the angle between two straight lines, provided that a straight line can be drawn making right angles with one of these curves at its point of intersection with the other. This is my reason for believing that I shall have given here a sufficient introduction to the study of curves when I have given a general method of drawing a straight line making right angles with a curve at an arbitrarily chosen point upon it. And I dare say that this is not only the most useful and most general problem in geometry that I know, but even that I have ever desired to know.

[2] Let  $CE$  be the curved line. It is desired to draw a straight line at right angles to it, through the point  $C$ . I suppose the problem to have been solved, and that the sought-for line is  $CP$ , which I prolong to the point  $P$  where it meets the straight line  $GA$ . ( $GA$  is the line to whose points all those of  $CE$  are referred; so that putting  $MA$  or  $CB$  equal to  $y$ , and  $CM$  or  $BA$  equal to  $x$ , I have some equation showing the relation between  $x$  and

it should be, this circle must cut the curve not only at  $C$  but also in another point. Now if this circle cuts  $CE$ , the equation involving  $x$  and  $y$  as unknown quantities (supposing  $PA$  and  $PC$  known) must have two unequal roots. Suppose, for example, that the circle cuts the curve in the points  $C$  and  $E$ . Draw  $EQ$  parallel to  $CM$ . Then  $x$  and  $y$  may be used to represent  $EQ$  and  $QA$  respectively in just the same way as they were used to represent  $CM$  and  $MA$ ; since  $PE$  is equal to  $PC$  (being radii of the same circle), if we seek  $EQ$  and  $QA$  (supposing  $PE$  and  $PA$  given) we shall get the same equation that we should obtain by seeking  $CM$  and  $MA$  (supposing  $PC$  and  $PA$  given). It follows that the value of  $x$ , or  $y$ , or any other such quantity, will be two-fold in this equation, that is, the equation will have two unequal roots. If the value of  $x$  be required, one of these roots will be  $CM$  and the other  $EQ$ ; while if  $y$  be required, one root will be  $MA$  and the other  $QA$ . It is true that if  $E$  is not on the same side of the curve as  $C$ , only one of these will be a true root, the other being drawn in the opposite direction, or less than nothing. The nearer together the points  $C$  and  $E$  are taken however, the less difference there is between the roots; and when the points coincide, the roots are exactly equal, that is to say, the circle through  $C$  will touch the curve  $CE$  at the point  $C$  without cutting it.

[5] Furthermore, it is to be observed that when an equation has two equal roots, its left-hand member must be similar in form to the expression obtained by multiplying by itself the difference between the unknown quantity and a known quantity equal to it; and then, if the resulting expression is not of as high a degree as the original equation, multiplying it by another expression which will make it of the same degree. This last step makes the two expressions correspond term by term.

[6] For example, I say that the first equation found in the present discussion, namely

$$y^2 + \frac{qry - 2qvy + qv^2 - qs^2}{q - r},$$

must be of the same form as the expression obtained by making  $e = y$  and multiplying  $y - e$  by itself, that is, as  $y^2 - 2ey + e^2$ . We may then compare the two expressions term by term, thus: Since the first term,  $y^2$ , is the same in each, the second term,  $\frac{qry - 2qvy}{q - r}$ , of the first is equal to  $-2ey$ , the second term of the second; whence,

solving for  $v$ , or  $PA$ , we have  $v = e - \frac{r}{q}e + \frac{1}{2}r$ ; or, since we have assumed  $e$  equal to  $y$ ,

$v = y - \frac{r}{q}y + \frac{1}{2}r$ . In the same way, we can find  $s$  from the third term,  $e^2 = \frac{qv^2 - qs^2}{q - r}$ ;

but since  $v$  completely determines  $P$ , which is all that is required, it is not necessary to go further.

### 11.E3 Isaac Barrow on areas and tangents

Let  $ZGE$  be any curve of which the axis is  $VD$  and let there be perpendicular ordinates to this axis ( $VZ, PG, DE$ ) continually increasing from the initial ordinate  $VZ$ ; also let  $VIF$  be a line such that, if any straight line  $EDF$  is drawn perpendicular to  $VD$ , cutting
